Abstract

Industrial motor-driven systems use more than 2194 billion kWh annually on a global basis and offer one of the largest opportunities for energy savings.¹ The International Energy Agency estimates that optimization of motor driven systems could reduce global electricity demand by 7% through the application of commercially available technologies and using well-tested engineering practices. Yet many industrial firms remain either unaware of or unable to achieve these energy savings.

The same factors that make it so challenging to achieve and sustain energy efficiency in motor-driven systems (complexity, frequent changes) apply to the production processes that they support. Yet production processes typically operate within a narrow band of acceptable performance. These processes are frequently incorporated into ISO 9000/14000 quality and environmental management systems, which require regular, independent audits to maintain ISO certification, an attractive value for international trade.

It is our contention that a critical step in achieving and sustaining energy efficiency of motor-driven systems specifically, and industrial energy efficiency generally, is the adoption of a corporate energy management standard that is consistent with current industrial quality and environmental management systems such as ISO.

Several energy management standards currently exist (US, Denmark, Ireland, Sweden) and specifications (Germany, Netherlands) others are planned (China, Spain, Brazil, Korea). This paper presents the current status of energy management standards development internationally, including an analysis of their shared features and differences, in terms of content, promulgation, and implementation. The purpose of the analysis is to describe the current state of “best practices” for this emerging area of energy efficiency policymaking and to suggest next steps toward the creation of a truly international energy management standard that is consistent with the ISO principles of measurement, documentation, and continuous improvement.

Introduction

Industrial motor-driven systems consume more than 60% of global manufacturing electricity annually and offer one of the largest opportunities for energy savings². The International Energy Agency estimates that up to 7% of global electricity demand could be saved by more energy-efficient motors and motor systems. At present, both markets and policy makers tend to focus exclusively on individual system components, such as motors or pumps, with an improvement potential of 2%–5% instead of optimizing systems.

¹ 2194 billion kWh annually based on analysis conducted by Lawrence Berkeley National Laboratory, Alliance to Save Energy, and Energetics July 2004, updated 2005.

² *Ibid.*

Equipment manufacturers have steadily improved the performance of individual system components (such as motors, pumps and compressors) but these components only provide a service to the users' production process when operating as part of a system.

While the energy efficiency of components, such as motors, may be quite high, when viewed as an entire system their overall efficiency is quite low. Motor systems, on average, lose 55% of their input energy before reaching the process or end use.³ Some of these losses are inherent in the energy conversion process; for example, a compressor typically loses 80% of its input energy to low grade waste heat as the incoming air is converted from atmospheric pressure to the desired system pressure.⁴ Many losses, however, can be avoided through the application of commercially available technologies and good engineering practices. The potential for motor system energy efficiency improvement has been well-documented at 20% or more by program experiences in the US, UK, China, and elsewhere.

The same factors that make it so challenging to achieve and sustain energy efficiency in motor-driven systems (complexity, frequent changes) apply to the production processes that they support. Yet production processes typically operate within a narrow band of acceptable performance. These processes are frequently incorporated into ISO 9000/14000 quality and environmental management systems, which require regular, independent audits to maintain ISO certification, an attractive value for international trade.

Motor System Energy Efficiency: Potential vs Reality

The energy savings potential of motor systems remains largely unrealized because it is deeply embedded in industrial operational and management practices. Industrial motor-driven systems are ubiquitous in the manufacturing environment, but their applications are highly varied. System optimization cannot be achieved through component standards or labeling or "one size fits all" approaches. The presence of energy-efficient components, while important, provides no assurance that a motor-driven system will be energy-efficient. In fact, the misapplication of energy-efficient equipment in industrial motor systems is common. The disappointing results from these misapplications can provide a serious disincentive for any subsequent effort toward system optimization.

Even when plant engineering and operations staff recognize the importance of optimizing a system and identify system optimization projects, they frequently experience difficulty in achieving management support. The reasons for this are many, but central among them are two: 1) a management focus on production as the core activity, not energy efficiency and 2) the existence of a budgetary disconnect in industrial facility management between capital projects (incl. equipment purchases) and operating expenses. Incentive structures within companies are frequently structured to reward lowest first cost rather than life cycle cost purchasing practices, which can also impede motor system optimization. As a further complication, experience has shown that most optimized systems lose their initial efficiency gains over time due to personnel and production changes. Since system optimization knowledge typically resides with an individual who has received training, detailed operating instructions are not integrated with quality control and production management systems.

The authors have previously presented the case for addressing these concerns through an *Industrial Standards Framework*, which would establish a link between International Organization for Standardization (ISO) management systems and industrial system optimization. The Framework includes energy efficiency standards, policies, training, and tools that have the net effect of making system optimization for energy efficiency as much a part of typical industrial operating practices as waste reduction and inventory management. The purpose of this paper is to provide a detailed look at a key

³ U.S. Department of Energy, (2004), *Energy Loss Reduction and Recovery in Industrial Energy Systems*, http://www.eere.energy.gov/industry/energy_systems/analysis.html

⁴ Compressed Air Challenge™ and the US Department of Energy (2003), *Improving Compressed Air System Performance: A Sourcebook for Industry*, http://www1.eere.energy.gov/industry/bestpractices/techpubs_compressed_air.html

element of the Framework, an effective energy management standard, by examining the current status of energy management standards in six countries (China, Denmark, Ireland, Sweden, Netherlands, and the United States). Particular attention will be given to their link to ISO 9000/14000 quality and environmental management systems, their policy and program context, and their possible role in realizing the potential from motor system optimization.

Elements of an Effective Energy Management Standard

The purpose of an energy management standard is to provide guidance for industrial facilities to integrate energy efficiency into their management practices, including fine-tuning production processes and improving the energy efficiency of industrial systems. Although the focus of this paper is industrial energy efficiency, it is important to note that the energy management standards referenced here are equally applicable to commercial, medical, and government facilities.

An energy management standard requires a facility to develop an energy management plan. In companies without a plan in place, opportunities for improvement may be known but may not be promoted or implemented because of organizational barriers. These barriers may include a lack of communication among plants, a poor understanding of how to create support for an energy efficiency project, limited finances, poor accountability for measures, or perceived risk in changing the status quo.

All of the energy management standards studied for this paper use the “plan-do-check-act” approach as illustrated in the diagram below from the Danish DS 2403:2001, Energy Management-Specification.

Energy management — step by step

A. Energy management can be described as a targeted process consisting of 5 distinct stages. Each stage comprises a number of steps.

B. The process can be repeated for new projects and new objectives ...

Source: Danish DS 2403:2001, Energy Management-Specification.

Typical features of an energy management standard include:

- a strategic plan that requires measurement, management, and documentation for continuous improvement for energy efficiency;
- a cross-divisional management team led by an energy coordinator who reports directly to management and is responsible for overseeing the implementation of the strategic plan;
- policies and procedures to address all aspects of energy purchase, use, and disposal;
- projects to demonstrate continuous improvement in energy efficiency;
- creation of an Energy Manual, a living document that evolves over time as additional energy saving projects and policies are undertaken and documented;
- identification of key performance indicators, unique to the company, that are tracked to measure progress; and
- periodic reporting of progress to management based on these measurements.

In addition, for Denmark, Ireland, and Sweden, the standard includes explicit reference to a commitment to adhere to other applicable relevant regulations and requirements that pertain to the company's energy use.

A successful program in energy management begins with a strong commitment to continuous improvement of energy efficiency. A first step once the organizational structure (energy coordinator, management team) has been established is to conduct an assessment of the major energy uses in the facility to develop a baseline of energy use and set goals for improvement. The selection of key performance indicators and goals help to shape the development and implementation of an action plan. An important aspect for ensuring the successes of the action plan is involving personnel throughout the organization. Personnel at all levels should be aware of energy use and goals for efficiency. Staff need to be trained in both skills and general approaches to energy efficiency in day-to-day practices. In addition, performance results should be regularly evaluated and communicated to all personnel, recognizing high achievement. The use of energy monitoring and process control systems can play an important role in energy management and in reducing energy use.

Table 1 compares the elements of the energy management standards in the countries studied. For all five countries with existing energy management standards (or specifications), the standard has been developed to be entirely compatible with the ISO quality management program (ISO 9001:2000) and environmental management program (ISO 14001). In the case of Denmark, Ireland, and Sweden, the assumption is that industrial facilities participating in ISO 14001 will integrate the requirements of the standard into their existing management documentation and procedures.

Table 1. Energy Management Standards, Details

Participating Countries	Management Commitment Required	Develop energy management plan	Establish energy use baseline	Identify Energy Coordinator	Establish Cross-Divisional Implementation Team	Emphasis on Continuous Improvement	Document Energy Savings	Establish Performance Indicators & Energy Saving Targets	Document & Train Employees on Procedural/ Operational Changes	Specified Interval for Re-evaluating Performance	Reporting to Public Entity Required	Energy Savings Validated or Certified	Year Published	Approx Market Penetration by Industrial Energy Use

1 Certification is required for companies participating in voluntary agreements (also specified interval in Sweden). In Denmark, Netherlands & Sweden linked to tax relief eligibility.

2 As of 2002, latest date for which data is available

3 Netherlands has an Energy Management System, not a standard, per se, developed in 1998 and linked to Long Term Agreements in 2000.

4 800 companies representing 20% of energy use have LTAs and must use the Energy Management System. The 150 most energy intensive companies, representing 70% of the energy use, have a separate, more stringent, benchmarking covenant and are typically ISO 14000 certified, but are not required to use the EM System.

5 To date, the US government has encouraged energy management practices, but not use of the standard, therefore market penetration has been very limited. Program policies new in 2007 are designed to address this.

Supportive Policies and Programs

In the six countries studied, the energy management standards are designed to be applicable to all types and sizes of companies; however, in each instance the largest, most energy intensive industries are the focus of additional programs and initiatives. By concentrating efforts on these large energy users, policy makers seek the greatest reduction in industrial energy consumption and overall GHG emissions. Not surprisingly, the proportionally greatest impact on industrial energy consumption has been in Denmark, which has had financial incentives since 1992, in the form of a CO₂ –tax rebate, coupled with voluntary agreements and, as of 2001, energy management standards. An entirely different approach has been taken in the US, which has concentrated on educating industry about system energy efficiency opportunities. The US has not explicitly promoted use of its energy management standard nor offered either financial incentives or penalties for meeting energy reduction targets. As a result, relatively few plants are using the energy management standard. Table 2 below provides a comparison of these supporting policies.

Table 2. Energy Management Standards, Programmatic Context

Participating Countries	Voluntary or Mandatory Standard	Financial Incentives for Compliance	Technical Assistance Available	Penalties for Non-Compliance	Recognition Program	Linked to Voluntary Agreement	Training Available on Standard Compliance	Industrial Systems Training Available	Case Studies Published	Targeted Plants
<i>Existing</i>

United States	vol	no	yes	no	planned	no	planned	yes	yes	yes
<i>Under Development</i>										
China	vol	info not yet available						yes		yes

1 Denmark has had a CO₂ tax since 1992 that affects larger industries. Tax relief is linked to participation in a voluntary agreement.

2 Netherlands' Long Term Agreement participants must develop an energy management plan

3 Sweden has had a energy tax since 1/2005. Tax relief for process-related electricity linked to participation in a voluntary agreement.

4 Ireland plans to expand training offerings

5 Netherlands has training available on specific topics

Denmark

Denmark has had a CO₂ tax in place since 1992 on all energy sources in Denmark. Because of concerns that the tax would make energy-intensive Danish industries non-competitive, the government introduced voluntary agreements that offered a CO₂- tax rebate for adopting energy management practices and undertaking energy efficiency measures. To be eligible, companies had to be listed by the Danish Energy Authority as energy-intensive and the company's energy-tax load had to exceed 4 percent of the company's value added in the year prior to signing the agreement. These agreements have become an important driver in encouraging use of the energy management standard in Denmark. Energy-intensive companies that enter into agreements for tax benefits must implement all energy-efficiency measures related to heavy processes with a payback period of four years or less; for less energy intensive companies signing agreements, the implementation requirement extends to measures with payback periods of six years or less.

According to Persson and Grudbjorg [2006]-

The Danish Energy Authority has implemented several different policy measures to make industry invest in energy-efficiency and energy conservation actions. The most effective ones used by the Danish Energy Authority have been:

- Voluntary agreements
- Subsidies
- Information activities

The Danish Energy Authority, as the result of a 2002 evaluation of the voluntary agreement system, found that half of the companies involved had reduced their energy usage by 20%. According to Larsen, *et al* [2005]-

The intentions behind the development of Danish energy management during the last 10 years has been to transform it from a rather technical monitoring and measurement system to a management system with more focus on information, communication, internal and external audits and employee involvement.

The energy management system (introduced as a standard in 2001) was felt to be an advantage to the participating companies. Participating companies have cited other benefits such as better product quality, increased production capacity, and increased employee engagement. Active energy management in Denmark has been positively correlated for industrial firms with number of employees, CO₂- tax agreements, subsidies, and the number of environmental inspections by the local government. The role of training in system optimization techniques in achieving energy savings needs clarification.

Ireland

Sustainable Energy Ireland (SEI) has a well-integrated array of program offerings to encourage use of their energy management standard, IS 393, introduced in 2005. A three-day training session is offered on energy management that addresses topics such as energy management goals, benchmarking, establishing energy performance indicators, and an overview of energy improvement opportunities with a focus on motor driven systems. Companies are encouraged to join the Large Industry Energy Network (LIEN) to share and learn from each other during implementation of the energy management standard. The most energy intensive sites in Ireland (annual energy bill of €2 million or greater) are being recruited to participate in the Energy Agreements Programme, entering into an agreement with SEI that requires implementation of IS 393, including certification of compliance by an outside party. The target group comprises 60-100 industrial energy users, particularly those subject to the requirements of the EU-Emission Trading Scheme. As of January 2007, 25 companies were participating. Participants are eligible for an array of services to assist them in setting and meeting their energy management goals. Participation in a recognition program and case studies are also encouraged. A separate program for smaller companies is under development.⁵

Netherlands

In The Netherlands, guidance for establishing an Energy Management System based on the ISO standard for environmental management systems has been developed in support of the Long-Term Agreements. This Energy Management System Specification was developed in 1998 in cooperation with Bureau Veritas, an ISO 14001 certification institute, and introduced into the Long-Term Agreements (LTA) program activity in 2000. Companies that signed or joined LTA2 have the obligation to implement an energy management system within two years.

The 150 most energy intensive companies, representing 70% of total industrial energy use, have a separate bench marking covenant with the government. These industries are required to be among the

⁵ For more information, see <http://www.sei.ie/> and <http://www.sei.ie/index.asp?locID=158&docID=-1>

top 10% most energy efficient in their sector worldwide. Many of these companies are also ISO 14001 certified.⁶

Sweden

Sweden has had a voluntary agreement program since 1994, but only added an energy management standard as a program requirement in 2003. Prior to that time, the voluntary agreement had few incentives for participation and the results of the program could not be measured.⁷ In 2005, after Sweden imposed a tax on industrial process-related electricity, the Programme for Improving Energy Efficiency in Energy-Intensive Industries (PFE) was launched. Managed by the Swedish Energy Agency, the PFE offers reduced taxation for companies that introduce and obtain certification for a standardized energy management system and undertake electrical energy efficiency improvements. The program requires a five-year initial commitment, with specific milestones to report by the end of two years, as follows:

- implement the energy management standard that is certified by an accredited certification body;
- complete an in-depth energy audit and analysis to baseline use and identify improvement opportunities. A list of measures identified in the energy audit with a payback of three years or less must be submitted to the Swedish Energy Agency;
- establish procurement procedures that favor energy efficient equipment, and
- establish procedures for project planning and implementation.

By the end of five years, the company must implement the listed measures, demonstrate continued application of the energy management standard and procurement procedures, and assess the effects of project planning procedures. As of January, 2007, 126 companies had signed up to participate in PFE, representing approximately 50% of all industrial electricity use. To join, companies must be in certain eligible classes, use electricity in their manufacturing process, have energy costs of at least 3% of production value or pay at least 0.5% of value-added in energy-related taxes, and have the economic means to carry out the program. To assist companies in compliance, the government has published handbooks on energy management, energy audits and analysis, routines for purchasing and planning, and a template for calculating life cycle cost in accordance with program requirements. The role of training for participating companies needs to be clarified.⁸

United States

Georgia Institute of Technology (Georgia Tech) first developed a comprehensive energy management standard for industry in 2000 that has served as a model for several subsequent national standards. Although the standard was adopted by the American National Standards Institute (ANSI), it has received little public recognition or support and is not widely used in the US. The US has, however, developed a great deal of technical capability in industrial energy efficiency, especially motor, steam, and process heating systems.

Since 1993, the US Department of Energy (USDOE) has been developing and offering a wide array of technical training and publications to assist industrial facilities in becoming more energy efficient through its BestPractices program. In October 2005, USDOE initiated a program to offer an Energy Saving Assessment (ESA) demonstration for steam or process heating systems in 200 plants with an annual energy use of 2TBtu or higher. Eight months after completion of the assessments, 134 plants had reported almost \$222 million worth of energy savings recommendations either completed, underway, or

⁷ Linden and Carlsson-Kanyama, 2002, as cited in Price 2005

⁸ For more information, see <http://www.stem.se/> and http://www.stem.se/WEB/STEMEx01Eng.nsf/F_PreGen01?ReadForm&MenuSelect=F78F2B2CB1DE4525C12570FB00428BD8

planned. Based on the success of the first year, the program was expanded in 2006 to include motor systems.⁹

In 2002, the US Environmental Protection Agency (USEPA) began a voluntary program, Climate Leaders, which works with companies to develop long-term comprehensive climate change strategies. Using the GHG emissions protocol developed by the World Resources Institute and the World Business Council for Sustainable Development, 59 companies have set and report progress on a corporate-wide GHG reduction goal to be achieved over 5 to 10 years. These goals are evaluated against the projected performance of the relevant sector. In 2003, the USEPA began offering information on energy management guidelines and benchmarking as part of its ENERGY STAR for Industry program. The program also includes energy performance indicators for selected industries that companies can use to benchmark their performance, gaining recognition if they are in the upper quartile.¹⁰

Collectively, these activities encourage companies to manage energy, but do not explicitly encourage use of an energy management standard. However, recently USDOE and USEPA have joined together to develop a collaborative program to certify plants for energy efficiency that implement energy management standards, based on an updated version of the Georgia Tech/ANSI energy management standard. This program is expected to greatly increase use of the standard by US industries.

China

The China Standard Certification Center (CSC) has been authorized by the Chinese government to develop a series of national energy management standards. Three standards are planned for release by March 2008: Management System for Energy - Requirements, Management System for Energy - Guidelines for Performance, and Management System for Energy - Guidelines for Auditing. The draft Requirements standard has much in common with the other energy management standards in use elsewhere.

The Chinese government has selected the Top-1000 Energy Consuming Enterprises as a major source of potential energy savings to meet national energy reduction goals. The Chinese energy management standards will be completed in 2008 and will be added to the portfolio of policy instruments and program offerings to assist these plants in meeting their goals.

Going Global: An International Approach to Industrial Energy Management

As shown in Table 1, the existing energy management standards have many features in common. This is not accidental. All the standards reviewed in this paper have been developed by individuals well-versed in the ISO management model for continuous improvement. The US standard, developed by Georgia Tech/ANSI, was based on ISO management principles. The Danish standard, issued a year later, has most of the same features and makes explicit references to ISO 14001. Both the Irish and Swedish standards acknowledge their similarity and relationship to the Danish standard. The Chinese standard now under development is using the Georgia Tech/ANSI standard as a reference. Brazil, Spain, and Korea have also initiated work on an energy management standard.

The European Committee for Standardization (CEN) and the European Committee for Electrotechnical Standardization (CENELEC) have formed a task force and undertaken development of a set of three European standards related to energy management including: energy service companies – ESCOs, energy managers and experts, and energy management systems. The Task Force 189- Energy Management convened in November 2006 with 24 participants from 10 countries, and decided to create three ad hoc Project Teams to develop the standards. The standard on energy management systems has been assigned to Sweden and will be a simple compilation of existing Danish, Swedish and Irish

⁹ For more information about BestPractices see <http://www1.eere.energy.gov/industry/bestpractices/>; for information about Energy Saving Assessments, see <http://www1.eere.energy.gov/industry/saveenergynow/>

Standards and the Netherlands Specification, conform to the ISO 14 000 structure and requirement. It will also take in account the German VDI Specification on EMS.

A dialogue on international harmonization of energy management standards has recently been initiated by the ISO Secretariat, UNIDO, CEN, and the countries with experience with energy management standards who participated in a UNIDO experts' group meeting on this topic in March 2007. Developing countries have requested UNIDO's support to conduct a feasibility study to identify opportunities, costs, and barriers resulting from widespread adoption of an international energy management standard. UNIDO has made a commitment to proceed with both the feasibility study and with an experts working group to begin the international process for harmonization among existing energy management standards in the coming year.
